Independent Component Analysis in the Detection of Intrinsic Connectivity Networks

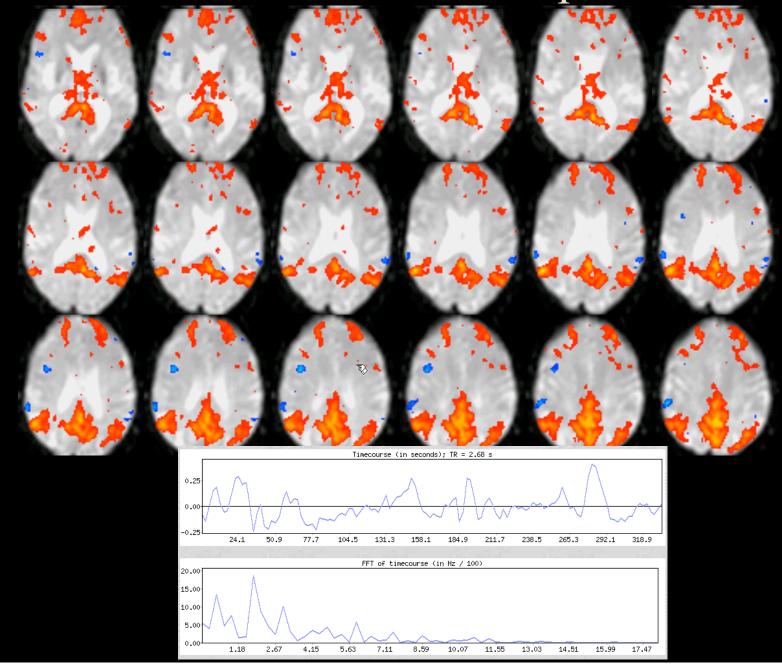

- ICA separates the fMRI signal into (largely) non-overlapping spatiotemporal components
- Data-driven but can also be hypothesis-driven
- Allows for better removal of noisy components (motion, scanner drift, etc).
- Reliably extracts default-mode network (and others) en bloc

# Healthy Skepticism

"For example, is this merely an effect of mechanical symmetry between the hemispheres in response to cardiac and CSF pulsations? Can the response be explained by vasomotor oscillations ...? Is this response modulated by levels of consciousness? Are crossing white matter pathways truly necessary ...?"

# Resting-State fMRI and ICNs

- Spontaneous, low-frequency BOLD fluctuations reveal canonical networks (of which the DMN is only one of 15-20)
- ROI and ICA-based approaches are complementary
- Yes, there is noise mixed in with the signal
- Beneath the noise is an elegantly structured, mysterious, but reliable, neuronal phenomenon of unclear etiology and limitless functional relevance

#### What Role Does the Default-Mode Network Play?

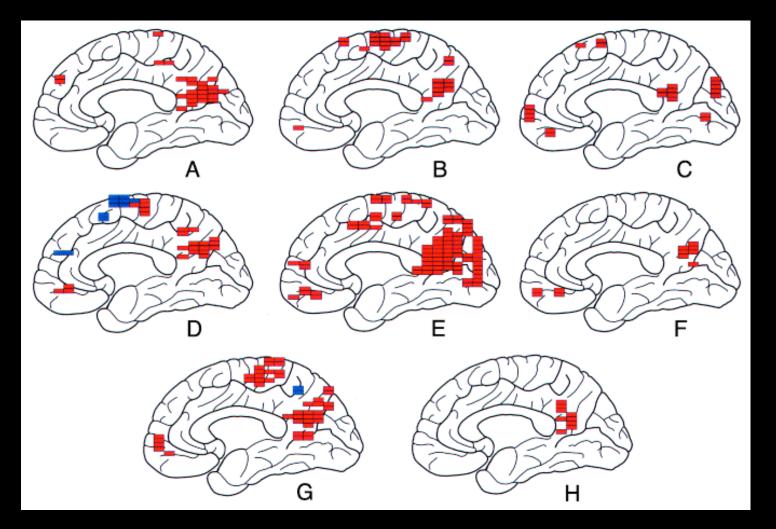

- Function is hard, by definition, to assess directly with behavioral paradigms
- Rely instead on
  - lesion studies or lack thereof
  - rare task activation paradigms with default-modish activation maps
  - comparisons of network activity between two groups or states differing in some fundamental attribute
  - interactions within network and between the default mode and other networks
